View the connections between alerts in network traffic-based alert groups in Express List by using Link View. Network traffic-based alert groups are created by analyzing network traffic connections between processes across hosts.

Service candidates identified by ML Service Mapping, group alerts based on network traffic connections between processes. Link View shows a contextual view of network incidents based on these groups of directly connected processes. Service candidates are potential collections of processes within your IT environment that are identified based on their network connections and interactions.

Figure 1. Sample network traffic-based alert group in Link View

In this sample Link View of a network traffic-based alert group, the dashed lines indicate that there are connected processes running on the CIs. Attributes linked by a solid line share one or more alerts.
